FIELD OF THE INVENTION

This invention generally relates to a pylon or barrier arrangement which is recessed into the ground or other surface, including a post-like pylon which is raised into an extended position for control of vehicular or pedestrian traffic.

5

10

15

BACKGROUND OF THE INVENTION

The control of vehicular traffic often requires that certain lanes be closed to traffic and that traffic be temporarily be redirected to other lanes to accommodate variances in traffic flow, or as a result of repair work. It is also often necessary or desirable to control the ingress and egress of pedestrians in certain public areas, such as in amusement parks, college campuses, and tourist areas. This type of traffic control is often achieved by manually positioning freestanding markers, such as upright cones or drums, at desired locations and then removing or shifting same as necessary. solution is time consuming, and in the situation where cones are placed directly on roadways to control or restrict vehicular traffic, poses a hazard to workers who must necessarily enter the roadway where vehicles are often traveling at high speeds.

As such, various pop-up traffic control devices have been developed which include a cartridge or housing embedded beneath the ground or roadway surface and a pylon or bollard which is housed within the below-ground cartridge when not in use. The pylon is remotely activated to raise same into an uppermost position for controlling or restricting traffic. A number of such traffic control devices are installed in side-by-side spaced relation with one another along a roadway or other area to provide traffic guidance. For the purpose of raising and lowering the pylon, many of these

conventional devices include a rotatably driven threaded shaft which is mounted within the embedded lower cartridge. The shaft engages with a screw nut which is fixed to the pylon so that the nut and pylon traverse up or down on the shaft depending upon the rotational direction thereof. Examples of such an arrangement are disclosed in U.S. Patent No. 5 425 595, and French Patent No. 2650-009.

The primary disadvantage of devices utilizing a screw-type mechanism to actuate the pylon is end-loading. More specifically, abrupt axial end-loading of the pylon occurs when the pylon is driven downwardly, for example by a vehicle tire, when the pylon is rising from the roadway surface. This downward driving of the pylon and nut often results in a stripped nut, or more significantly, the downward driving of the shaft itself which can cause damage to the motor and/or other internal components mounted within the lower area of the cartridge, such as the control board. These types of arrangements also include less than desirable sealing capabilities, which can result in the accumulation of dirt and grit on the threaded shaft and thus an abraded or damaged screw nut and/or shaft.

35

Other conventional pop-up traffic control devices utilize pneumatic devices to raise and lower the pylon. However, these arrangements often require close tolerances within their construction to prevent leakage, and involve increased costs associated with installation of appropriate pneumatic lines in the roadway.

With traffic control devices which are permanently installed in the roadway, exposure of the device to freezing temperatures can also present problems, such as ice formation adjacent the top of the cartridge which can restrict movement of the pylon. Conventional solutions to this problem included providing a heater disposed exteriorly of the pylon so as to heat the top cover or

flange located adjacent the roadway surface to melt the ice. However, since the top cover is typically of significant width and thickness dimensions, a high-wattage heater and considerable warm-up time are necessary. In addition, angled road grades often create complications with existing devices, wherein the interference between the top flange or plate and the pylon can jam or stall the motor.

The present invention relates to a retractable-type barrier or pylon arrangement including an extendible and retractable pylon or cylinder which is actuated by a drive mechanism capable of compensating for an abrupt axial downward movement of the pylon, thus avoiding damage to the drive mechanism itself and/or other internal components of the system. The invention also incorporates an improved sealing arrangement which minimizes the amount of water and debris entering the arrangement from the surface, and an improved heating system which requires less energy.

10

15

20

25

30

35

More particularly, one aspect of the invention relates to a barrier arrangement including a generally tubular housing mounted within the ground so that an upper end thereof is generally flush with the ground surface. A post is disposed within the housing and is telescopingly movable relative thereto between an uppermost position wherein the post extends upwardly from the upper end of the housing and above the ground surface and a lowermost position wherein the post is disposed substantially completely within the housing and beneath the ground surface. A drive mechanism moves the post between the uppermost and lowermost positions, which drive mechanism includes a rotatable drive shaft having a smooth outer surface, and a block-like member disposed in clamping engagement with the smooth outer surface and non-movably fixed to the post. Rotation of the drive shaft causes displacement of the block-like member and

the post relative to and along the drive shaft to move the post into one of the uppermost and lowermost positions.

Another aspect of the invention relates to a retractable pylon arrangement including a generally upright cartridge embedded within an opening in the ground so that an uppermost end thereof is substantially level with the ground surface. A pylon is disposed in a telescoping manner within the housing and is movable between an extended position wherein the pylon is cantilevered upwardly from the ground and a retracted position wherein the pylon is positioned within the cartridge and beneath the ground surface. A remotelycontrolled drive mechanism moves the post between the extended and retracted positions, and an annular flange closes off the uppermost end of the cartridge. The flange has an inner terminal periphery disposed in surrounding relation with the pylon which defines an opening to permit movement of the pylon between the extended and retracted positions. A flexible annular seal member is mounted on the inner periphery of the flange and extends inwardly so as to maintain contact with an outer surface the pylon during movement thereof.

10

15

20

25

30

35

A further aspect of the invention relates to a pylon arrangement for controlling vehicular traffic including a generally hollow housing structure fixed within the ground in a generally upright manner, and an elongate pylon mounted for movement into the housing structure into a retracted storage position and for movement out of the housing structure into an extended position for controlling traffic. A heating unit is disposed within the pylon which when energized effectively heats an outer wall of the pylon and prevents seizure of the pylon due to ice build-up at least adjacent the ground surface.

                                    Referring to Figure 3, the upper end of drive shaft
                              18 MOUNTS thereon a thrust bearing 84. A heating unit 85
                             is mounted within the interior of pylon tube 40 on the
                             side of the thrust bearing 84. In the illustrated
                            embodiment, the heating unit 85 is a low-wattage, rubber
                           encapsulated, 24 Volt heater. Further, a lighting
                          arrangement 86 is provided within pylon tube 40.
                       10
                         lighting arrangement 86 includes a LED light cluster
                        Mounted to the thrust bearing 84 just below the roadway
                       Surface 19 so as to illuminate the entire pylon tube 40
                      when in the upwardly extended position (Figures I and 4).
                     The bearing 84 in the illustrated embodiment is lined
                    With Teflon to permit low-friction rotation of the shaft
                   18 relative to bearing 84, so that heating unit 85 and
                  lighting arrangement 86 are maintained essentially
             50
                     The pylon arrangement 10 in the illustrated
               embodiment is controlled from a remote location with an
              electronic control panel (not shown) Which communicates
             With the control board 55A either wirelessly Via radio
            signals or by means of a direct electrical connection.
                The Motor 55, control board 55A, heating unit 85,
          lighting arrangement 86 are electrically connected via
         Wiring 95 (shown in dotted lines) to a power pack or
         module 96 (shown schematically) mounted adjacent the
        ground surface 19 and connected to a power source.
      Wiring 95 leading to lighting arrangement 86 and heating
      unit 85 may be encased within flexible tubing 96 to
     protect the wiring and to minimize wear thereof due to
    Movement of the pylon 12. This wiring 95 within tube 40
   May be routed to the exterior of tube 40 by extending the
  wiring downwardly through opening 42 in base 41, through
35
 an Orifice (not shown) in hub 43 and then outwardly
```

through an opening (not shown) in inner tube 14. The wiring 95 within lower chamber 83 is also routed through an opening (not shown) through the wall of inner tube 14. Likewise, wiring 95 routed between inner and outer tubes 13 and 14 is routed through an opening (not shown) through the wall of outer tube 13 to power pack 96. It will be appreciated that the openings in inner and outer tubes 14 and 13 for routing wiring 95 are sealed around the respective wires to prevent entry of water or other contaminants. Communication cabling may also be routed through power pack 96 to control board 55A. The arrangement 10 is also typically connected to other pylon arrangements 10 via electrical and communication cabling.

As mentioned above, the cartridge 11 is mounted below ground level by embedding same in a pre-formed hole. If desirable or necessary, gravel or other material, such as concrete, may be used as filler around the outer surface of outer tube 13 to stably position the cartridge 11 in the ground. The cartridge 11 is mounted within the ground at a depth so that the top flange or cover 30 is substantially flush with the roadway or ground surface 19.

In operation, when raising of the pylon or pylon 12 from the lowermost position illustrated in Figure 3 is desirable or necessary, the appropriate input command is entered into the control board 55A via a remotely-located control panel (not shown) to energize motor 55 and rotate the drive shaft 18. Upon rotation of the drive shaft 18, the linear drive 54 and pylon 12 translate upwardly relative to drive shaft 18. The respective upper and lower switches or sensors 28 and 28A are mounted on inner tube 14 in axial locations which correspond to the axial position of the magnet 50 when the pylon 12 is in the extended and retracted positions, respectively. Once the pylon 12 has reached the upper position wherein the upper surface of hub 43 abuts or is disposed closely adjacent

```
stop blocks 50A and magnet 50 is axially adjacent upper
                                                                Sensor 28, sensor 28 senses magnet 50 and emits a signal
                                                               to deenergize motor 55 and stop further upward
                                                             advancement of the pylon 12 relative to shaft 18.
                                                          28 also indicates that the pylon 12 is in the up or
                                                         fully-extended position. A grouping of pylons 12 in
                                                       their uppermost raised positions can thus be used to
                                                     restrict travel within certain traffic lanes or areas,
                                                   whether vehicular traffic or pedestrian traffic.
                                                 illustrated embodiment, the approximate height of the
                                               DYION 12 in the up position as measured from ground level
                                             19 is approximately 3 feet. The pylon 12 can then be
                                            lowered into the retracted position shown in Figure 3 by
                                         entering the appropriate input command into the control
                                       panel to effectively reverse the polarity of the motor
                                  15
                                      55, which reverses the rotational direction of drive
                                   Shaft 18 and causes the pylon 12 and drive 54 to traverse
                                  downwardly relative to shaft 18. Once the pylon 12 is
                                has reached the down or lower position wherein magnet 50
                              is axially adjacent lower sensor 28A, sensor 28A senses
                        50
                            magnet 50 and emits a signal to deenergize motor 55.
                          Sensor 28A also indicates that the pylon 12 is in the
                        retracted position. As such, a transitional position of
                       the pylon 12 can be detected when no signal is received
                     from either of sensors 28 and 28A.
                            In the event of a sudden downward driving movement
                 of the upper end of the pylon tube 40 during movement
               thereof into the upwardly extended position (for example
             when the pylon 12 is less than about six inches above the theteor the of the continuous 
           top flange 30), for example when a vehicle tire or other
         object forces the pylon tube 40 downwardly, the linear
       drive 54 acts as a clutch which decouples the pylon 12
     from the drive shaft 18. More specifically, the contact
   between the roller bearings 64 and 65 of the linear drive
  Stand the smooth drive shaft 18 provides a sufficient
level of linear thrust required to raise and lower the
```

pylon 12. However, the drive 54 acts as a linear clutch by slipping downwardly on the drive shaft 18 when the pylon 12 is acted upon by an axial load which exceeds a predetermined threshold as determined by the adjusted clamping force of blocks 56, 60 on shaft 18. When this predetermined threshold is exceeded, the pylon 12 breaks free of its positive engagement with the shaft 18 and translates downwardly relative to the shaft 18 until the source of overload is removed. Once the downward force on the pylon 12 is removed, the pylon 12 once again translates up the shaft 18 to its maximum height above the ground surface 19. Thus, damage to the interior components located within the inner tube 14 is avoided, for example, damage to the motor 55 and/or control board 55A within lower compartment 83. Damage to the drive mechanism 17 itself is also avoided.

35

In one application of the illustrated embodiment, the end loading force applied to the pylon 12 and transmitted through the drive shaft 18 due to an abrupt downward movement of pylon 12 is minimal. In contrast, if such an abrupt axial force is applied to a conventional arrangement utilizing a threaded shaft and screw nut, the shaft and nut can be damaged, in addition to the damage which can be caused by the downward driving of the shaft into the lower end of the cartridge.

Further, for vehicle traffic applications, the pylon tube 40 is preferably constructed of a flexible, yet semi-rigid and durable and resilient material, such as polyethylene plastic. As such, when a lateral force is applied to the pylon tube 40 whether in the fully extended position or when rising from the cartridge 11, the tube 40 will yield under the lateral force and bend sidewardly. When the force is removed, the pylon tube 40 will essentially regain its original upright configuration. In addition, it is also advantageous to

provide the pylon tube 40 with a bright color, such as yellow or orange, so that same is easily visible.

The sealing arrangement 33 located at the upper end of the cartridge 11 is also advantageous. Water and debris can severely limit the reliability and operation of a below-ground pylon arrangement, and preventing water and contaminants from entering the interior of the arrangement is thus highly desirable. The flexible seals 35 and 36 as shown in Figures 3 and 4 maintain contact with the outer surface of the pylon tube 40 regardless of 10 the position thereof, i.e. whether the pylon tube 40 is in the fully retracted or extended position, or moving between these two positions. The flexible seals 35, 36 significantly minimize intrusion of debris and liquid into the arrangement throughout the life-cycle thereof. 15 However, in time and through normal usage, the seals 35 and 36 wear and the roundness of the pylon tube 40 changes due to repeated collisions with vehicles. the drainage holes 16 in the inner tube 14 allow the escape of fluid from the upper compartment 82. 20 addition, the brush or wiper 45 cleans the smooth shaft 18 of any debris during each stroke of the pylon 12, and the lip seal 81 prevents entry of water and debris into the lower compartment 83. In contrast, pylon arrangements utilizing a threaded drive shaft arrangement 25 are prone to jamming during operation due to the accumulation of contaminants on the threads of the drive shaft. Thus, the arrangement according to the invention is more reliable than a threaded drive arrangement in a wet, grit-filled environment. 30

Variations in road grade are common and to accommodate same, the inner diameters of the upper and lower flanges 30 and 22 of the pylon arrangement 10 are significantly larger than the outer diameter of the pylon tube 14 such that a horizontal gap 91 is defined therebetween. This gap 91 allows for at least some

35

angular and/or axial misalignment between the pylon tube 40 and the flanges 30 and 22. Further, the flexible seals 35, 36 extend over this gap 91 and permit angular misalignment of the tube 40 and the flanges 30 and 22. This arrangement is an improvement over conventional devices in which interference between the top plate and the pylon often prevent the pylon from rising, and cause warping or bending of the top plate due to overloading.

5

35

Further, the heating unit 85 is advantageously located within the interior of the pylon tube 40. This 10 arrangement heats the air within the pylon tube 40 so that heat is transferred via conduction through the wall of the plastic pylon tube 40. This heating of the pylon tube 40 itself, combined with the upward thrusting force of the arrangement 10 according to the invention (i.e. in 15 the illustrated embodiment approximately sixty pounds), is sufficient to allow the pylon tube 40 to break through a considerable glazing of ice on the surface 19 of the roadway. Since ice formation at the interface between the pylon tube 40 and the upper flange 30 poses the 20 greatest potential for seizure of the arrangement 10 during harsh weather conditions, the mounting of the heating unit 85 at the top of the drive shaft 18 just below the roadway surface 19 is an optimum location. actuation of the heating unit 85 is controlled via the 25 control board 55A, and may be controlled with a timer which actuates the heating unit 85 intermittently based upon weather conditions, or as otherwise appropriate. The lighting arrangement 86 which is also mounted within the interior of the pylon tube 40 atop drive shaft 18 and 30 just below the roadway surface 19 illuminates the entire pylon tube 40 when in the fully extended position.

Some applications of the pylon arrangement 10 according to the invention for the control of vehicular traffic include toll collection lanes, weighing stations, parking lots, railroad crossings, reversible traffic

lanes, HOV lanes, and tunnel and bridge entrances. For pedestrian applications, the flexible pylon tube 40 may be utilized or can be replaced with a more rigid pylon which could potentially include hooks or supports for handrails, lights or lasers, for example. The arrangement according to the invention can be used to remotely control pedestrian flow in amusement parts, stadiums, tourist and shopping areas by controlling groups of pylon arrangements. When use of the pylons is unnecessary, the pylons are unobtrusively stored beneath ground level.

It will be appreciated that the linear drive 54 disclosed herein is only one example of a preferred commercially available product sold under the name "ZERO-15 MAX" which may be utilized according to the invention. Other types of linear drives which may conceivably be utilized in accordance with the invention are disclosed in U.S. Patent Nos. 4 411 166 and 3 272 021, which are hereby incorporated by reference herein.

10

Although a particular preferred embodiment of the invention has been disclosed in detail for illustrative purposes, it will be recognized that variations or modifications of the disclosed apparatus, including the rearrangement of parts, lie within the scope of the present invention.
